A GENERAL FORM OF INTEGRAL.

BY P. J. DANIELL.

Introduction. The idea of an integral has been extended by Radon, Young, Riesz* and others so as to include integration with respect to a function of bounded variation. These theories are based on the fundamental properties of sets of points in a space of a finite number of dimensions. In this paper a theory is developed which is independent of the nature of the elements. They may be points in a space of a denumerable number of dimensions or curves in general or classes of events so far as the theory is concerned. It follows that, although many of the proofs given are mere translations into other language of methods already classical (particularly those due to Young), here and there, where previous proofs rested on the theory of sets of points, new methods have been devised (see, for example, theorems 3(3), 3(4), 5(1)).

Moore† has developed a theory of a similarly general nature, but restricts himself to the use of relatively uniform sequences. This concept is not used nor is it necessary in the following paper. We consider a group of elements $p$, which may be whatever we choose, and certain classes of functions $f(p)$ of those elements so that to every element $p$ of the group there exists a real number $f(p)$ (which may be infinite in certain cases). To each function of a certain class there corresponds a real number $S(f)$ or $I(f)$ which is defined so as to satisfy certain conditions. $S(f)$ is a generalized Stieltjes integral, while $I(f)$ may be called the positive integral and the latter possesses correlates of nearly all the properties of the Lebesgue integral. It is shown that any $I$-integral is an $S$-integral while any $S$-integral is expressible as the difference of two $I$-integrals.

Two symbols have been taken over from symbolic logic, namely those for logical sum and logical product. The concepts involved are used extensively by Young and by the author and the symbols have been introduced to save space and to clarify the reasoning.

The reader is referred also to Hildebrandt‡ for references to an exten-

---

279
sive literature on generalized integrals. Fréchet considers a general integral but does not discuss existence theorems so completely.*

1. Logical addition.—$f(p)$ is said to be the logical sum of $f_1(p)$ and $f_2(p)$ if, for each $p$, the value of $f(p)$ is the greater of the values of $f_1(p)$, $f_2(p)$ for that $p$. Symbolically

$$f(p) = f_1(p) \lor f_2(p).$$

Logical product.—$f(p)$ is said to be the logical product of $f_1(p)$ and $f_2(p)$ if, for each $p$, the value of $f(p)$ is the less of the values of $f_1(p)$, $f_2(p)$ for that $p$. Symbolically

$$f(p) = f_1(p) \land f_2(p).$$

Then

1.1

$$f_1 \lor f_2 + f_1 \land f_2 = f_1 + f_2,$$

1.2

$$(- f_1) \lor (- f_2) = -(f_1 \land f_2).$$

It is assumed that there is an initial class $T_0$ of numerically valued functions $f(p)$ of the elements $p$ where $T_0$ is closed with respect to the operations:—multiplication by a constant $(C)$, addition $(A)$, logical addition $(G)$ and logical multiplication $(G')$. It is further assumed that the functions of $T_0$ are limited, that is corresponding to any $f(p)$, a finite number $K(f)$ can be found such that $|f(p)| < K(f)$ for all $p$. The following properties $C$, $A$, $L$, $P$, $M$ are essential in what follows. $f, f_1, f_2, \cdots f_n, \cdots$ represent functions of the elements $p$ belonging to the class $T_0$.

Let $U(f)$ be a functional operation on $f$, then each of the properties is as follows:

(C)

$$U(cf) = cU(f),$$

where $c$ is constant;

(A)

$$U(f_1 + f_2) = U(f_1) + U(f_2);$$

(L) If $f_1(p) \geq f_2(p) \geq \cdots$ and if $\lim f_n(p) = 0$ for all $p$, $\lim U(f_n) = 0$.

(P) If $f(p) \equiv 0$ for all $p$, $U(f) \equiv 0$.

(M) A functional operation $M(\varphi)$ exists for all functions of the type $|f|$, where $f$ is of class $T_0$, such that if $\varphi \leq \psi$, $M(\varphi) \leq M(\psi)$, and such that $|U(f)| \leq M(|f|)$. The $I$-integral, or $I(f)$, is a functional on functions of $T_0$ satisfying $(C)(A)(L)(P)$, while the $S$-integral satisfies $(C)(A)(L)(M)$.

The class $T_0$ is also restricted so as to include only such functions $f$ that $I(f)$, $M(|f|)$ are finite for each $f$, though these integrals will not be bounded in their class. A few instances of the theory are as follows:

(a) The element $p$ is a real number $x$ in an interval $(a, b)$. The

class $T_0$ is the class of continuous functions. Then the Riemann integral is an $I$-integral and the Stieltjes integral an $S$-integral. The extension to the class of summable functions leads to Lebesgue or Young integrals in the former case and to Radon or Young-Stieltjes integrals in the latter.

(b) $p$ is a complex of numbers $(x_1, x_2, \cdots, x_n)$ or a point in a finite number of dimensions. Again $T_0$ is the class of continuous functions in a fundamental interval which may have infinite bounds. Again we obtain the Radon or Young-Stieltjes integral as an $S$-integral. The modular integral $\int f(p) \mid dv(p) \mid$ is an $I$-integral.

In place of continuous functions we may take $T_0$ to be the class of step-functions (functions constant over each of a finite number of sub-intervals), or else polygonal functions, or the class of polynomials together with their combinations by logical addition and multiplication. The resulting integral is the same. The Fréchet and Moore integrals (see references above) are also special instances.

(c) To show that our analysis applies also to integrals of a really new kind we may consider a particular example, namely

$$\int_0^1 f(x) d \log x.$$  

Here $\log x$ is not a function of limited variation. Take $T_0$ as the class of functions $f(x)$ such that $f(x)/x$ is continuous. Substitute $t = - \log x$, and the integral may be defined as

$$\int_0^\infty [f(e^{-t}) e^t] e^{-t} dt.$$  

Since $f(x)/x$ is continuous,

$$|f(e^{-t}) e^t| \leq \text{some } K,$$

or the integral is absolutely convergent.

An example is interesting where a linear functional operation satisfies $(C)$ $(A)$ $(P)$ but not $(L)$, and therefore is not an instance. Suppose $T_0$ is the class of step functions $f(x)$ defined in the interval $0 \leq x \leq 1$, and let $c$ be a number between 0 and 1, then we can define

$$U(f) = \lim_{\epsilon \to 0} f(c - \epsilon).$$

This $U(f)$ satisfies $(C)$ $(A)$ $(P)$, but consider

$$f_n(x) = 0, \quad 0 \leq x \leq c - \frac{1}{n},$$

$$= 1, \quad c - \frac{1}{n} < x < c,$$

$$= 0, \quad c \leq x \leq 1.$$
Evidently \( f_1 \geq f_2 \geq \cdots \), and \( \lim f_n(x) = 0 \) for all \( x \). But \( U(f_n) = 1 \) for all \( n \), or, \( \lim U(f_n) = 1 \) instead of 0.

2. Relations between \( S(f) \) and \( I(f) \).—In this and the next two paragraphs all functions mentioned will be of class \( T_0 \).

2(1). If \( f(p) \leq g(p) \), \( I(f) \leq I(g) \). For \( g - f \) is of class \( T_0 \) and \( g(p) - f(p) \geq 0 \).

\[ \therefore I(g) - I(f) = I(g - f) \]

\[ \geq 0 \quad \text{[By (C), (A)]} \]

\[ |f| = f \vee (-f) \] must be of class \( T_0 \), then in condition \( (M) \), \( I(|f|) \) satisfies the conditions to be satisfied by \( M(|f|) \).

2(2).

\[ |I(f)| \leq I(|f|). \]

For \( -|f| \leq f \leq +|f| \).

\[ \therefore -I(|f|) \leq I(f) \leq I(|f|) \quad \text{By 2(1).} \]

Then \( I(f) \) satisfies the condition \( (M) \) and it already satisfies \( (C) (A) (L) \), hence any \( I \)-integral is an \( S \)-integral.

3. If \( f(p) \geq 0 \) for all \( p \) we define \( I_1(f) \) as the upper bound of \( S(\varphi) \) for all functions \( \varphi \) of class \( T_0 \) such that \( 0 \leq \varphi \leq f \).

This upper bound exists for

\[ S(\varphi) \leq M(|\varphi|) \quad \text{by (M).} \]

\[ M(|\varphi|) = M(\varphi) \quad \text{for } 0 \leq \varphi, \]

\[ \leq M(f) \quad \text{for } \varphi \leq f. \]

\[ \therefore S(\varphi) \leq M(f). \]

\( I_1(f) \) is called the positive integral associated with \( S \).

3(1). If \( f(p) \geq 0 \) for all \( p \), \( I_1(f) \geq 0 \). \( 0 = 0 \cdot f \) is a function of class \( T_0 \) and \( S(0) = 0 \). But 0 is one of the functions \( \varphi \) by which \( I_1(f) \) is defined.

\[ \therefore I_1(f) \geq 0. \]

Thus \( I_1(f) \) satisfies condition \( (P) \).

3(2). If \( f(p) \geq 0 \) for all \( p \) and \( c \) is a positive constant,

\[ I_1(cf) = cI_1(f). \]

For if \( 0 \leq \varphi \leq f, 0 \leq c\varphi \leq cf \), and vice versa. Also \( S(c\varphi) = cS(\varphi) \).

3(3). If \( f_1(p) \geq 0, f_2(p) \geq 0 \) for all \( p \), \( I_1(f_1 + f_2) = I_1(f_1) + I_1(f_2) \). Firstly, \( I_1(f_1 + f_2) \geq I_1(f_1) + I_1(f_2) \). For if \( 0 \leq \varphi_1 \leq f_1, 0 \leq \varphi_2 \leq f_2, 0 \leq \varphi_1 + \varphi_2 \leq f_1 + f_2. \)

\[ \therefore I_1(f_1 + f_2) \geq S(\varphi_1 + \varphi_2), \text{ or } S(\varphi_1) + S(\varphi_2). \]
But this is true however we vary \( \varphi_1, \varphi_2 \), hence

\[
I_1(f_1 + f_2) \equiv I_1(f_1) + I_1(f_2).
\]

Secondly,

\[
I_1(f_1 + f_2) \equiv I_1(f_1) + I_1(f_2).
\]

Let \( \varphi \) be any function such that \( 0 \equiv \varphi \equiv f_1 + f_2 \), then \( \varphi - f_1 \equiv f_2 \),

\[
\therefore (\varphi - f_1) \lor 0 \equiv f_2,
\]

\[
\varphi = \varphi \land f_1 + (\varphi - f_1) \lor 0.
\]

For if \( \varphi(p) \equiv f_1(p) \) for a particular \( p \), on the right-hand side the first term is \( f_1 \) and the second \( \varphi - f_1 \), while if \( \varphi(p) \equiv f_1(p) \) the first term is \( \varphi \) and the second 0. Now

\[
0 \equiv \varphi \land f_1 \equiv f_1 \quad 0 \equiv (\varphi - f_1) \lor 0 \equiv f_2.
\]

\[
\therefore S(\varphi \land f_1) \equiv I_1(f_1), \quad S[(\varphi - f_1) \lor 0] \equiv I_1(f_2).
\]

\[
\therefore S(\varphi) \equiv I_1(f_1) + I_1(f_2).
\]

But we may vary \( \varphi \) in any way so long as \( 0 \equiv \varphi \equiv f_1 + f_2 \).

\[
\therefore I_1(f_1 + f_2) \equiv I_1(f_1) + I_1(f_2).
\]

From what has been proved firstly and secondly it follows that

\[
I_1(f_1 + f_2) = I_1(f_1) + I_1(f_2).
\]

3(4). If \( f_1 \equiv f_2 \equiv \cdots \) and \( \lim f_n = 0 \) for all \( p \), \( \lim I_1(f_n) = 0 \). \( I_1(f_n) \) is defined as the upper bound of \( S(\varphi_n) \), where \( 0 \equiv \varphi_n \equiv f_n \). Hence given any positive \( e \) we can find \( \varphi_n \) \( (0 \equiv \varphi_n \equiv f_n) \) such that

\[
I_1(f_n) < S(\varphi_n) + 2^{-n}e.
\]

**Lemma.** Given that

\[
I_1(f_{n-1}) < S(\psi_{n-1}) + e_{n-1}, \quad I_1(f_n) < S(\varphi_n) + 2^{-n}e,
\]

and that

\[
f_n \leq f_{n-1}, \quad 0 \leq \psi_{n-1} \leq f_{n-1}, \quad 0 \leq \varphi_n \leq f_n.
\]

Then

\[
I_1(f_n) < S(\psi_{n-1} \land \varphi_n) + e_{n-1} + 2^{-n}e.
\]

Since

\[
0 \leq \psi_{n-1} \leq f_{n-1}, \quad 0 \leq \varphi_n \leq f_n \leq f_{n-1}, \quad 0 \leq (\psi_{n-1} \lor \varphi_n) \leq f_{n-1}.
\]

\[
\therefore S(\psi_{n-1} \lor \varphi_n) \leq I_1(f_{n-1}) < S(\psi_{n-1}) + e_{n-1},
\]

\[
\psi_{n-1} \land \varphi_n = \psi_{n-1} + \varphi_n - (\psi_{n-1} \lor \varphi_n) \quad \text{[By 1(1)].}
\]

\[
\therefore S(\psi_{n-1} \land \varphi_n) = S(\psi_{n-1}) + S(\varphi_n) - S(\psi_{n-1} \lor \varphi_n) > S(\varphi_n) - e_{n-1}.
\]
\[ I_1(f_n) < S(\varphi_n) + 2^{-n}e < S(\psi_{n-1} \land \varphi_n) + e_{n-1} + 2^{-n}e, \]
which proves the lemma.

For each \( f_n \) in the sequence choose the appropriate \( \varphi_n \) so that
\[ I_1(f_n) < S(\varphi_n) + 2^{-n}e. \]
Let
\[
\psi_1 = \varphi_1, \quad \psi_n = \psi_{n-1} \land \varphi_n \quad (n = 2, 3, \ldots), \\
e_1 = e/2, \quad e_n = e_{n-1} + 2^{-n}e \quad (n = 2, 3, \ldots).
\]
Then, using the Lemma successively with \( n = 2, 3, \ldots \), we get
\[ I_1(f_n) < S(\psi_n) + e_n, \quad e_n = e(1/2 + 1/4 + \cdots + 2^{-n}) < e. \]
\[ \therefore I_1(f_n) < S(\psi_n) + e. \]
Moreover \( 0 \leq \psi_n \leq \varphi_n \leq f_n \), and \( \lim f_n = 0 \), therefore \( \lim \psi_n = 0 \).
\[ \psi_1 \geq \psi_2 \geq \cdots \quad \text{and} \quad \lim \psi_n = 0. \]
\[ \therefore \lim S(\psi_n) = 0 \quad \text{[By (L)].} \]
\[ \therefore \lim I_1(f_n) \leq e. \]
But \( e \) was any positive quantity.
\[ \therefore \lim I_1(f_n) = 0. \]

Hence \( I_1(f) \) satisfies the condition \( (L) \).

If \( f = \varphi - \psi \), where \( \varphi \geq 0, \psi \geq 0 \), by definition
\[ I_1(f) = I_1(\varphi) - I_1(\psi). \]

This definition is self-consistent, for if
\[ f = \varphi_1 - \psi_1 = \varphi_2 - \psi_2, \quad \varphi_1 + \psi_2 = \varphi_2 + \psi_1, \]
\[ I_1(\varphi_1) + I_1(\psi_2) = I_1(\varphi_2) + I_1(\psi_1) \quad \text{[By 3(3)].} \]
\[ \therefore I_1(\varphi_1) - I_1(\psi_1) = I_1(\varphi_2) - I_1(\psi_2). \]

\( I_1(f) \) satisfies condition \( (C) \). For if \( c \) is positive
\[ I_1(cf) = I_1(c\varphi) - I_1(c\psi) = cI_1(\varphi) - cI_1(\psi) \quad \text{[By 3(2)].} \]
\[ = cI_1(f). \]

If \( c \) is negative,
\[ I_1(cf) = I_1(-c\psi) - I_1(-c\varphi) \]
\[ = -cI_1(\psi) - [-cI_1(\varphi)] \quad \text{[By 3(2)].} \]
\[ = cI_1(f). \]

If \( c = 0 \), \( I_1(cf) = I_1(0) = 0 = 0 \cdot I_1(f) \).
$I_1(f)$ satisfies condition (A). For we have

$$I_1(f_1 + f_2) = I_1(\varphi_1 + \varphi_2) - I_1(\psi_1 + \psi_2)$$

$$= I_1(\varphi_1) + I_1(\varphi_2) - I_1(\psi_1) - I_1(\psi_2) \quad \text{[By 3(3)]}$$

$$= I_1(f_1) + I_1(f_2).$$

We have already proved that $I_1(f)$ also satisfies conditions (L) (P). Hence $I_1(f)$ is an $I$-integral.

4. We define further

$$I_2(f) = I_1(f) - S(f),$$

the negative integral associated with $S$. Also we define

$$I(f) = I_1(f) + I_2(f) = 2I_1(f) - S(f),$$

the modular integral associated with $S$. Evidently $I_2(f)$, $I(f)$ satisfy all the conditions for $I$-integrals. Another definition of the modular integral $I(f)$ when $f$ is non-negative is the upper bound of $S(\varphi)$ for all functions $\varphi$ of class $T_0$ such that $-f \leq \varphi \leq f$. For then

$$0 \leq \varphi + f \leq 2f, \quad S(\varphi) = S(\varphi + f) - S(f).$$

Varying $\varphi$, keeping $f$ fixed, we see that the upper bound of $S(\varphi)$ is equal to

$$I_1(2f) - S(f) = 2I_1(f) - S(f) = I(f).$$

4(1). $|S(f)| \leq I(|f|)$, if $I$ is the modular integral associated with $S$. For

$$|S(f)| = |I_1(f) - I_2(f)| \leq |I_1(f)| + |I_2(f)|$$

$$\leq I_1(|f|) + I_2(|f|) \quad \text{[By 2(2)]}$$

or $I(|f|)$. It can be seen that if we extend the definitions of $I_1(f), I_2(f)$ to functions of a wider class $T$ so as still to satisfy (C)(A) (L) (P), and if we define

$$S(f) = I_1(f) - I_2(f), \quad I(f) = I_1(f) + I_2(f),$$

$S(f)$ will satisfy (C) (A) (L) (M) and $I(f)$ will satisfy (C) (A) (L) (P).

5. Extension to class $T_1$ for any $I$-integral. If $f_1 \leq f_2 \leq \cdots$ is a non-decreasing sequence of functions of class $T_0$, $\lim f_n$ exists (if we allow $+\infty$ as a value) and we say that $\lim f_n = f$ is of class $T_1$.

Then

$$I(f_1) \leq I(f_2) \leq \cdots,$$

and $\lim I(f_n)$ exists (if we allow $+\infty$ as a value).
5(1). If \( f_1 \leq f_2 \leq \cdots \) are of class \( T_0 \), and if \( \lim f_n \geq \) some function \( h \) of class \( T_0 \), \( \lim I(f_n) = I(h) \). Let \( g_n = f_n \land h \). Then \( g_n \) is of class \( T_0 \) and since \( \lim f_n \geq h \), \( \lim g_n = h \). Also \( f_{n-1} \leq f_n \), therefore \( g_{n-1} \leq g_n \).

\[ \therefore \quad h - g_1 \geq h - g_2 \geq \cdots \quad \text{and} \quad \lim (h - g_n) = 0. \]

\[ \therefore \quad \lim I(h - g_n) = 0 \quad \text{[By (L)].} \]

\[ \therefore \quad \lim I(g_n) = I(h). \]

But \( f_n \geq g_n \) or \( I(f_n) \geq I(g_n) \)

\[ \therefore \quad \lim I(f_n) \geq \lim I(g_n) \quad \text{or} \quad I(h). \quad \text{[By 2(1)].} \]

5(2). If \( f_1 \leq f_2 \leq \cdots \), \( g_1 \leq g_2 \leq \cdots \) are of class \( T_0 \), and if 

\[ \lim f_n \geq \lim g_n, \quad \text{then} \quad \lim I(f_n) \geq \lim I(g_n). \]

For \( \lim f_n \) is of class \( T_1 \) and \( \geq \lim g_n \), and therefore \( \geq g_n \).

\[ \therefore \quad \lim I(f_n) \geq \lim I(g_n) \quad \text{[By 5(1)].} \]

\[ \therefore \quad \lim I(f_n) \geq \lim I(g_n). \]

5(3). If \( f_1 \leq f_2 \leq \cdots \), \( g_1 \leq g_2 \leq \cdots \) are of class \( T_0 \) and if 

\[ \lim f_n = \lim g_n, \quad \text{then} \quad \lim I(f_n) = \lim I(g_n). \]

Apply 5(2) twice.

We define \( I(f) = \lim I(f_n) \), if \( f \) is of class \( T_1 \) and defined by the non-decreasing sequence \( (f_n) \) of functions of class \( T_0 \). By 5(3) this definition will be self-consistent. By 5(1), if \( f \geq 0 \), \( I(f) \geq 0 \). Hence condition \((P)\) is satisfied. Evidently conditions \((A)\) \((C)\) will be satisfied so long as in \((C)\) the constant \( c \) is positive.

**Note.** We have allowed \( \lim I(f_n) \) to be \(+ \infty \) and this necessitates a reconsideration of the above theorems. In 5(1), \( h \) is of class \( T_0 \) and therefore \( \lim I(h) \) is finite, or the statement will hold even if \( \lim I(f_n) = + \infty \). In 5(2) the theorem must be taken to mean, in the case where either \( \lim I(f_n) \) or \( \lim I(g_n) \) is \(+ \infty \), that at least \( \lim I(f_n) \) is \(+ \infty \). In 5(3) if either limit is \(+ \infty \) so is the other.

If \( I(f) = \lim I(f_n) \) is finite and \( f \) is of class \( T_1 \) we say that \( f \) is summable.

5(4). If \( f_1 \leq f_2 \leq \cdots \) is a nondecreasing sequence of functions of class \( T_1 \), then \( \lim f_n = f \) is also of class \( T_1 \) and \( I(f) = \lim I(f_n) \). For any integer \( r \), \( f_r \) is of class \( T_1 \) and is the limit of a nondecreasing sequence of functions of class \( T_0 \),

\[ f_{r,1} \leq f_{r,2} \leq \cdots \leq f_{r,s} \leq \cdots. \]

Let \( g_n \) be the logical sum of all functions \( f_{r,s} \) for which \( r \leq n, \ s \leq n \). Then \( g_n \) is of class \( T_0 \) and \( g_n \equiv g_{n+1} \).
A GENERAL FORM OF INTEGRAL.

\[ \therefore \lim g_n \text{ is of class } T_1. \]

If \( r \leq n, f_{r,n} \leq f_r \leq f_n \).

\[ \therefore g_n \leq f_n \quad \text{and} \quad I(g_n) \leq I(f_n). \]

If \( r \leq n, g_n \geq f_{r,n} \)

\[ \therefore \lim g_n \geq \lim f_{r,n} \text{ or } f_r. \]

\[ \therefore \lim g_n \geq f_r \quad (r = 1, 2, \cdots) \]

and

\[ I(\lim g_n) \geq I(f_r). \]

\[ g_n \leq f_n, \quad \lim g_n \leq \lim f_n. \]

\[ \lim g_n \geq f_r. \]

\[ \therefore \lim g_n \geq \lim f_n. \]

\[ \therefore \lim g_n = \lim f_n. \]

But \( \lim g_n \) is of class \( T_1 \), therefore \( \lim f_n \) is of class \( T_1 \).

\[ I(f) = I(\lim g_n) \geq I(f_r) \text{ for all } r. \]

\[ \therefore I(f) \leq \lim I(f_n). \]

\[ I(f) = I(\lim g_n) \leq I(g_n). \]

But

\[ I(g_n) \leq I(f_n). \]

\[ \therefore I(f) \leq \lim I(f_n). \]

\[ \therefore I(f) = \lim I(f_n). \]

6. Semi-integrals. For any function \( f \) we define \( \tilde{I}(f) \), the upper semi-integral of \( f \), as the lower bound of \( I(\varphi) \) for all functions \( \varphi \) of class \( T_1 \), such that \( \varphi \geq f \).

6(1). If \( c \) is a positive constant, \( \tilde{I}(cf) = c\tilde{I}(f) \). For if \( \varphi \geq f \), \( c\varphi \geq cf \) and vice versa, and \( I(c\varphi) = cI(\varphi) \).

6(2)

\[ \tilde{I}(f_1 + f_2) \leq \tilde{I}(f_1) + \tilde{I}(f_2). \]

For if \( \varphi_1, \varphi_2 \) are any functions of class \( T_1 \) such that \( \varphi_1 \geq f_1, \varphi_2 \geq f_2, \varphi_1 + \varphi_2 \geq f_1 + f_2. \)

\[ \therefore \tilde{I}(f_1 + f_2) \leq I(\varphi_1 + \varphi_2), \text{ or } I(\varphi_1) + I(\varphi_2). \]

Varying \( \varphi_1, \varphi_2 \) independently, we obtain the theorem.

6(3). If \( f \leq g \) for all \( p \),

\[ \tilde{I}(f) \leq \tilde{I}(g). \]

For if \( \varphi \) is any function of class \( T_1 \) such that \( \varphi \geq g, \varphi \geq f \)

\[ \tilde{I}(f) \leq I(\varphi), \text{ etc.} \]
6(4). We define $\dot{I}(f) = -\dot{I}(-f)$; then $\dot{I}(f)$ is called the lower semi-integral of $f$, and $\dot{I}(f) \leq \dot{I}(f)$. For by 6(2)

$$0 = \dot{I}(0) = \dot{I}(f - f) \leq \dot{I}(f) + \dot{I}(-f) \quad \text{or} \quad \dot{I}(f) - \dot{I}(f).$$

6(5)

$$\dot{I}(f \lor g) + \dot{I}(f \land g) \leq \dot{I}(f) + \dot{I}(g).$$

For if $\varphi_1, \varphi_2$ are any functions of class $T_1$ such that $\varphi_1 \equiv f$, $\varphi_2 \equiv g$.

$$\varphi_1 \lor \varphi_2 \equiv f \lor g, \quad \varphi_1 \land \varphi_2 \equiv f \land g.$$

$\therefore \quad \dot{I}(f \lor g) + \dot{I}(f \land g) \leq \dot{I}(\varphi_1 \lor \varphi_2) + \dot{I}(\varphi_1 \land \varphi_2) \quad \text{or} \quad I(\varphi_1) + I(\varphi_2).$

For

$$\varphi_1 \lor \varphi_2 + \varphi_1 \land \varphi_2 = \varphi_1 + \varphi_2.$$

Varying $\varphi_1, \varphi_2$ independently, we obtain the theorem.

Corollary.

$$\dot{I}(\lfloor f \rfloor) - \dot{I}(\lceil f \rceil) \leq \dot{I}(f) - \dot{I}(f).$$

For

$$\lfloor f \rfloor = f \lor (-f), \quad -\lfloor f \rfloor = f \land (-f).$$

$\therefore \quad \dot{I}(\lfloor f \rfloor) + \dot{I}(-\lfloor f \rfloor) \leq \dot{I}(f) + \dot{I}(-f).$

7. Summability. If $\dot{I}(f) = I(f) = \text{finite}$, $f$ is said to be summable, and we define

$$I(f) = \dot{I}(f) = \dot{I}(f).$$

7(1). If $f$ is summable and $f \geq 0$ for all $p$, $\dot{I}(f) \geq \dot{I}(0)$ or $0$.

7(2). If $c$ is any constant and $f$ is summable, $cf$ is summable and $I(cf) = cI(f)$.

If $c$ is positive,

$$\dot{I}(cf) = c\dot{I}(f) = cI(f) \quad \text{[By 6(1)].}$$

$$-\dot{I}(cf) = \dot{I}(-cf) = cI(-f) = -cI(f).$$

$\therefore \quad \dot{I}(cf) = I(cf) = cI(f).$

If $c$ is negative,

$$\dot{I}(cf) = -c\dot{I}(-f) \quad \text{[By 6(1)].}$$

$$= cI(f)$$

$$-\dot{I}(cf) = \dot{I}(-cf) = -c\dot{I}(f). \quad \therefore \quad \text{etc.}$$

7(3). If $f_1, f_2$ are summable, so is $f_1 + f_2$ and $I(f_1 + f_2) = I(f_1) + I(f_2)$.

For

$$\dot{I}(f_1 + f_2) \leq \dot{I}(f_1) + \dot{I}(f_2) \quad \text{[By 6(2)],}$$

$$\text{or } I(f_1) + I(f_2).$$
A GENERAL FORM OF INTEGRAL.

\[-I(f_1 + f_2) = \hat{I}(f_1) + \hat{I}(f_2) \leq \hat{I}(f_1 - f_2) \leq \hat{I}(f_1) + \hat{I}(f_2) = -I(f_1) - I(f_2),\]

or \[-I(f_1) - I(f_2) \leq -I(f_1) - I(f_2).\]

\[\therefore \quad I(f_1 + f_2) \geq I(f_1) + I(f_2) \quad \therefore \quad \text{etc.}\]

\[\hat{I}(f_1 + f_2) \geq I(f_1 + f_2) \quad \therefore \quad \text{etc.}\]

7(4). If \(f\) is summable, so is \(|f|\) and \(|I(f)| \leq I(|f|)\). By 6(5) Cor.

\[\hat{I}(|f|) - \hat{I}(|f|) \leq \hat{I}(f) - \hat{I}(f) = 0.\]

But \(\hat{I}(|f|) \geq I(|f|)\). Hence the first part follows. Moreover,

\[-|f| \leq f \leq |f|.\]

\[\therefore -I(|f|) = \hat{I}(-|f|) \leq \hat{I}(f) \text{ or } I(f) \leq \hat{I}(|f|) \text{ or } I(|f|).

The second part follows immediately.

7(5). If \(f_1, f_2\) are summable, so are \(f_1 \lor f_2, f_1 \land f_2\). For by 6(5)

\[\hat{I}(f_1 \lor f_2) + \hat{I}(f_1 \land f_2) \leq \hat{I}(f_1) + \hat{I}(f_2), \text{ or } I(f_1) + I(f_2).

If we replace \(f_1\) by \(-f_1, f_2\) by \(-f_2\), we shall replace \(f_1 \lor f_2\) by \(-(f_1 \land f_2)\) and \(f_1 \land f_2\) by \(-(f_1 \lor f_2)\).

\[\therefore \quad \hat{I}(- (f_1 \land f_2)) + \hat{I}(- (f_1 \lor f_2)) \leq \hat{I}(- f_1) + \hat{I}(- f_2),\]

\[\therefore \quad I(f_1 \land f_2) + I(f_1 \lor f_2) \leq I(f_1) + I(f_2), \text{ or } I(f_1) + I(f_2).

\[\therefore \quad \hat{I}(f_1 \lor f_2) - \hat{I}(f_1 \land f_2) \leq \hat{I}(f_1 \land f_2) - \hat{I}(f_1 \lor f_2) \leq 0.\]

But each of these differences is non-negative, therefore they are both zero.

7(6). If \(f_1 \leq f_2 \leq \cdots\) is a nondecreasing sequence of summable functions, and if \(\lim I(f_n)\) is finite, \(I_n = f\) is summable, and \(I(f) = \lim I(f_n)\); while if \(\lim I(f_n) = +\infty, I(f) = +\infty\).

For \(-f \leq -f_n\).

\[\therefore \quad I(-f) \leq I(-f_n) \quad \text{[By 6(3)],}

\[\hat{I}(f) \leq I(f_n) \quad (n = 1, 2, \cdots).

\[\therefore \quad \hat{I}(f) \leq \lim I(f_n).

This proves the last part of the theorem. Given any positive \(e\), we can choose \(\varphi_1, \varphi_2, \cdots\) of class \(T_1\) such that

\[\varphi_1 \equiv f_1, \quad \varphi_2 \equiv f_2 - f_1, \quad \varphi_3 \equiv f_3 - f_2, \quad \cdots,\]
and so that

\[
I(\varphi_1) < I(f_1) + e/2,
I(\varphi_2) < I(f_2 - f_1) + e/4,
\]

\[\ldots \ldots \ldots \ldots \]

If \( n \geq 2 \), \( \varphi_n \equiv f_n - f_{n-1} \equiv 0 \). We define \( \psi_n = \varphi_1 + \varphi_2 + \cdots + \varphi_n \). Then \( \psi_n \) is of class \( T_1 \) and \( \psi_1 \equiv \psi_2 \equiv \cdots \). By 5(4), \( \lim \psi_n \) is of class \( T_1 \) and \( I(\lim \psi_n) = \lim I(\psi_n) \). \( \psi_n \equiv f_n \), or \( \lim \psi_n \equiv \lim f_n \) or \( f \).

\[
\therefore \quad I(f) \equiv I(\lim \psi_n) \quad \text{[By 6(3),}
\]

or \( \lim I(\psi_n) \).

\[
I(\psi_n) = I(\varphi_1) + I(\varphi_2) + \cdots + I(\varphi_n)
< I(f_1) + I(f_2 - f_1) + \cdots + I(f_n - f_{n-1})
+ e(\frac{1}{2} + \frac{1}{4} + \cdots + 2^{-n})
< I(f_n) + e.
\]

\[
\therefore \quad \lim I(\psi_n) \equiv \lim I(f_n) + e.
\]

\[
\therefore \quad I(f) \equiv \lim I(f_n) + e.
\]

But \( e \) is any positive quantity.

\[
\therefore \quad I(f) \equiv \lim I(f_n).
\]

We have already shown that \( I(f) \equiv I(f_n) \).

\[
\therefore \quad I(f) = I(f) = \lim I(f_n).
\]

\[
\therefore \quad \text{if } \lim I(f_n) \text{ exists, } f \text{ is summable and } I(f) = \lim I(f_n).
\]

7(7). If \( f_1, f_2, \ldots \) is a sequence of summable functions with limit \( f \), and if a summable function \( \varphi \) exists such that \( |f_n| \equiv \varphi \) for all \( n \), \( f \) is summable, \( \lim I(f_n) \) exists and \( = I(f) \). We must recall the method whereby the limit of a sequence is obtained. Let \( g_{r,s} \) be the logical sum of \( f_r, f_{r+1}, \ldots, f_{r+s+1} \); then \( g_{r,s} \equiv g_{r,s+1} \equiv \cdots \) with limit \( g_r \). Then \( g_r \equiv g_{r+1} \equiv \cdots \), and \( \lim g_r = f \), if \( \lim f_n = f \). Similarly we let \( h_{r,s} \) be the logical product of \( f_r, f_{r+1}, \ldots, f_{r+s} \) and then \( h_{r,s} \equiv h_{r,s+1} \equiv \cdots \) with limit \( h_r \). Then \( h_r \equiv h_{r+1} \equiv \cdots \), and \( \lim h_r = f \) if \( \lim f_n = f \). \( f_n \) is summable for all \( n \), therefore by 7(5), \( g_{r,s} \) is summable. Since \( f_n \equiv \varphi \), \( g_{r,s} \equiv \varphi \). \( \therefore \quad I(g_{r,s}) \equiv I(\varphi) \). Therefore \( g_r \) is summable by 7(6). Again \( g_{r,s} \equiv - \varphi \) or \( - g_{r,s} \equiv \varphi \). \( \therefore \quad - g_r \equiv \varphi \). \( \therefore \quad I(-g_r) \equiv I(\varphi) \). But

\[
- g_r \equiv - g_{r+1} \equiv \cdots
\]

with limit \( -f \). Therefore \( -f \) is summable by 7(6) and
\[ I(-f) = \lim I(-g_r). \]

Therefore by 7(2), \( f \) is summable and \( I(f) = \lim I(g_r) \). Given any positive \( \varepsilon \) we can find \( r_1 \), so that

\[ I(g_r) < I(f) + \varepsilon \quad (r \geq r_1). \]

Now

\[ f_r \leq g_r, \quad s \leq g_r. \]

\[ \therefore I(f_r) \leq I(g_r) \]

\[ < I(f) + \varepsilon \quad (r \geq r_1). \]

Similarly we can prove that \( h_r \) is summable and \( I(f) = \lim I(h_r) \). We can find \( r_2 \) so that

\[ I(h_r) > I(f) - \varepsilon \quad (r \geq r_2). \]

\[ f_r \geq h_r, \quad s \geq h_r. \]

\[ \therefore I(f_r) \geq I(h_r) \]

\[ > I(f) - \varepsilon \quad (r \geq r_2). \]

Therefore if \( r_0 \) is the greater of \( r_1 \) and \( r_2 \),

\[ |I(f_r) - I(f)| < \varepsilon \quad (r \geq r_0). \]

Hence \( \lim I(f_n) \) exists and equals \( I(f) \). From these theorems it follows that \( I(f) \) satisfies the conditions \((C)\) \((A)\) \((L)\) \((P)\), where the functions now belong to the class of summable functions.

8. \( S \)-integra ls. Associated with any \( S \)-integral \( S(f) \) for functions of class \( T_0 \) we have three \( I \)-integrals, namely \( I_1(f), I_2(f), I(f) \), such that

\[ S(f) = I_1(f) - I_2(f), \quad I(f) = I_1(f) + I_2(f). \]

If we extend our definitions of the \( I \)-integrals to functions of class \( T_1 \), we shall still have

\[ I(f) = I_1(f) + I_2(f). \]

8(1). If \( f \) is any function,

\[ \hat{I}_1(f) + \hat{I}_2(f) = \hat{I}(f). \]

For if \( \varphi \) is any function of class \( T_1 \) such that \( \varphi \geq f \),

\[ \hat{I}_1(f) + \hat{I}_2(f) \leq I_1(\varphi) + I_2(\varphi), \text{ or } I(\varphi). \]

Varying \( \varphi \), we obtain

\[ \hat{I}_1(f) + \hat{I}_2(f) \leq \hat{I}(f). \]

Again given any positive \( \varepsilon \) we can choose \( \varphi_1, \varphi_2 \) of class \( T_1 \) so that \( \varphi_1 \geq f, \varphi_2 \leq f \) and \( \hat{I}_1(f) > I_1(\varphi_1) - \frac{1}{2} \varepsilon, \hat{I}_2(f) > I_2(\varphi_2) - \frac{1}{2} \varepsilon \). Let \( \psi = \varphi_1 \land \varphi_2 \), then \( \psi \leq \varphi_1 \) and \( \psi \leq \varphi_2 \).
\[
\begin{align*}
\therefore \quad I_1(\varphi_1) + I_2(\varphi_2) & \equiv I_1(\psi) + I_2(\psi), \text{ or } I(\psi). \\
\therefore \quad \hat{I}_1(f) + \hat{I}_2(f) & > I(\psi) - \epsilon.
\end{align*}
\]

But \( \psi \geq f. \quad \therefore \quad I(\psi) \geq \hat{I}(f). \)

\[
\therefore \quad \hat{I}_1(f) + \hat{I}_2(f) > \hat{I}(f) - \epsilon.
\]

This is true for any positive \( \epsilon. \)

\[
\therefore \quad \hat{I}_1(f) + \hat{I}_2(f) \equiv \hat{I}(f).
\]

But we have already proved that

\[
\hat{I}_1(f) + \hat{I}_2(f) \equiv \hat{I}(f). \quad \therefore \text{ etc.}
\]

8(2). If \( f \) is summable \((I)\), it is summable \((I_1)\) and \((I_2)\), and

\[
I(f) = I_1(f) + I_2(f).
\]

For

\[
\hat{I}_1(f) + \hat{I}_2(f) = \hat{I}(f) = I(f).
\]

\[
\hat{I}_1(-f) + \hat{I}_2(-f) = \hat{I}(-f) = -I(f).
\]

\[
\therefore \quad \hat{I}_1(f) + \hat{I}_2(f) = I(f).
\]

\[
\therefore \quad \hat{I}_1(f) - \hat{I}_1(f) + \hat{I}_2(f) - \hat{I}_2(f) = 0.
\]

But each of these differences is non-negative, therefore each must be zero separately. Then \( f \) is summable \((I_1)\) and \((I_2)\)

\[
I(f) = \hat{I}_1(f) + \hat{I}_2(f) = I_1(f) + I_2(f).
\]

\textit{f is said to be summable \((S)\) if, and only if, it is summable \((I)\), where \( I \) is the modular integral associated with \( S \).} Hence if \( f \) is summable \((S)\), it is summable \((I_1)\) and \((I_2)\) by 8(2).

We define

\[
S(f) = I_1(f) - I_2(f).
\]

Then \( S(f) \) satisfies all the conditions \((C)\) \((A)\) \((L)\) \((M)\) for functions summable \((S)\).

Many of the theorems already obtained for the \( I\)-integral can be imme-
mediately stated also for the \( S\)-integral.

Thus 7(2, 3, 5, 7) are true if we replace \( I \) everywhere by \( S \). 7(4) becomes:

If \( f \) is summable \((S)\), so is \(|f|\), and

\[
|S(f)| \equiv I(|f|),
\]

where \( I \) is the modular integral associated with \( S \). 7(6) becomes:

If \( f_1 \leq f_2 \leq \cdots \) are summable \((S)\) and if \( \lim I(f_n) \) exists, where \( I \) is
the associate modular integral, then \( \lim f_n = f \) is summable \((S)\) and
\[
S(f) = \lim S(f_n).
\]

8(3). The necessary and sufficient condition that \( f \) be summable \((S)\) is that given any positive \( e \) there exists a function \( f_e \) of class \( T_0 \) such that
\[
\hat{I}(\|f - f_e\|) < e,
\]
where \( I \) is the modular integral associated with \( S \).

Also in this case
\[
S(f) = \lim_{e \to 0} S(f_e).
\]

The condition is sufficient for
\[
f = f_e + f - f_e \equiv f_e + |f - f_e|.
\]

\[
\therefore \hat{I}(f) \leq I(f_e) + \hat{I}(|f - f_e|) < I(f_e) + e.
\]

Similarly
\[
\hat{I}(-f) < I(-f_e) + e,
\]
\[
\hat{I}(f) > I(f_e) - e.
\]

\[
\therefore \hat{I}(f) - \hat{I}(f) < 2e.
\]

This is true for any positive \( e \), therefore \( \hat{I}(f) = I(f) \). They are also finite for \( I(f_e) \) and \( e \) are finite. Also
\[
| S(f) - S(f_e) | = | S(f - f_e) | \leq I(|f - f_e|) < e.
\]

\[
\therefore S(f) = \lim S(f_e).
\]

The condition is necessary, for given any positive \( e \) there exists a summable function \( \phi \) of class \( T_1 \) such that \( \phi \equiv f \) and
\[
\hat{I}(f) \leq I(\phi) < \hat{I}(f) + \frac{1}{2}e.
\]

\[
\hat{I}(\|\phi - f\|) = \hat{I}(\phi - f)
\]

(since \( \phi \equiv f \))
\[
\leq I(\phi) + \hat{I}(-f), \text{ or } I(\phi) - \hat{I}(f), \text{ or } \hat{I}(\phi) - \hat{I}(f),
\]
for \( f \) is summable.

\[
\therefore \hat{I}(\|\phi - f\|) < \frac{1}{2}e.
\]

\( \phi \) is summable and of class \( T_1 \), therefore there exists a function \( f_e \) of class \( T_0 \) such that \( f_e \equiv \phi \) and
\[
I(f_e) > I(\phi) - \frac{1}{2}e.
\]

Then
\[
I(\|\phi - f_e\|) < \frac{1}{2}e.
\]

\[
\therefore I(|f - f_e|) \leq \hat{I}(|\phi - f| + |\phi - f_e|)
\]
\[
\leq \hat{I}(|\phi - f|) + \hat{I}(|\phi - f_e|) < e.
\]
Evidently the condition for summability, or the class of summable functions depends both on the operation $S$ and on the class $T_0$.

9. Measure. It is usual, though not necessary, to define the integral in terms of the measure of certain fundamental sets. Let us suppose that the measures of a certain class of elementary, or initial sets, or collections $E$, of the $p$ are given. In connection with a collection $E$ we can define a function $= 1$ when $p$ belongs to $E$, $= 0$ otherwise. We can agree to call the measure of $E$, the integral of the corresponding function. The class $T_0$ is then taken as the class of all functions which are linear combinations of these elementary set-functions. It will then be closed with respect to the operations $(C)$ $(A)$. For any set $E$ whatever we can say that it is measurable if the corresponding function is summable, and we can identify its measure with the integral of that function. This question requires however a separate and careful consideration. The author wishes to point out, without proof, a simple manner in which the Stieltjes integral can be generalized.

In the ordinary Stieltjes integral \( \int_a^b f(x) d\alpha(x) \), $f(x)$ is a continuous function ($a \leq x \leq b$) and $\alpha(x)$ of limited variation, that is such that

$$\sum_{i=1}^{n} |\alpha(x_i) - \alpha(x_{i-1})| \leq M,$$

for all subdivisions $a = x_0 < x_1 < \cdots < x_n = b$. Suppose that $\gamma(x)$ is not a function of limited variation but that

$$\sum_{i=1}^{n} x_i |\gamma(x_i) - \gamma(x_{i-1})| \leq M,$$

for all subdivisions $0 = x_0 < x_1 < \cdots < x_n = 1$. Then if $f(x)/x$ is continuous ($0 \leq x \leq 1$), we can define

$$\int_0^1 f(x) d\gamma(x) = \int_0^1 \frac{f(x)}{x} x d\gamma(x).$$

Of course this is only a transformation of the integral, $\int_0^1 f(x) d\alpha(x)$, where $\alpha(x) = \int_0^x x d\gamma(x)$ is of limited variation. It shows nevertheless that so long as suitable restrictions are placed on the integrand, integrals similar to that of Stieltjes can be defined with respect to functions which are not of limited variation.

Rice Institute,
Houston, Texas.
